University of Miami

Hematology/Oncology Fellow

Mentor: Dickran Kazandjian, MD
Professor of Medicine
Division of Myeloma, Department of Medicine
Associate Director, Clinical Trials Research
Sylvester Myeloma Institute, Sylvester CCC
University of Miami, Miller School of Medicine

UNIVERSITY OF MIAMI
Myeloma Division

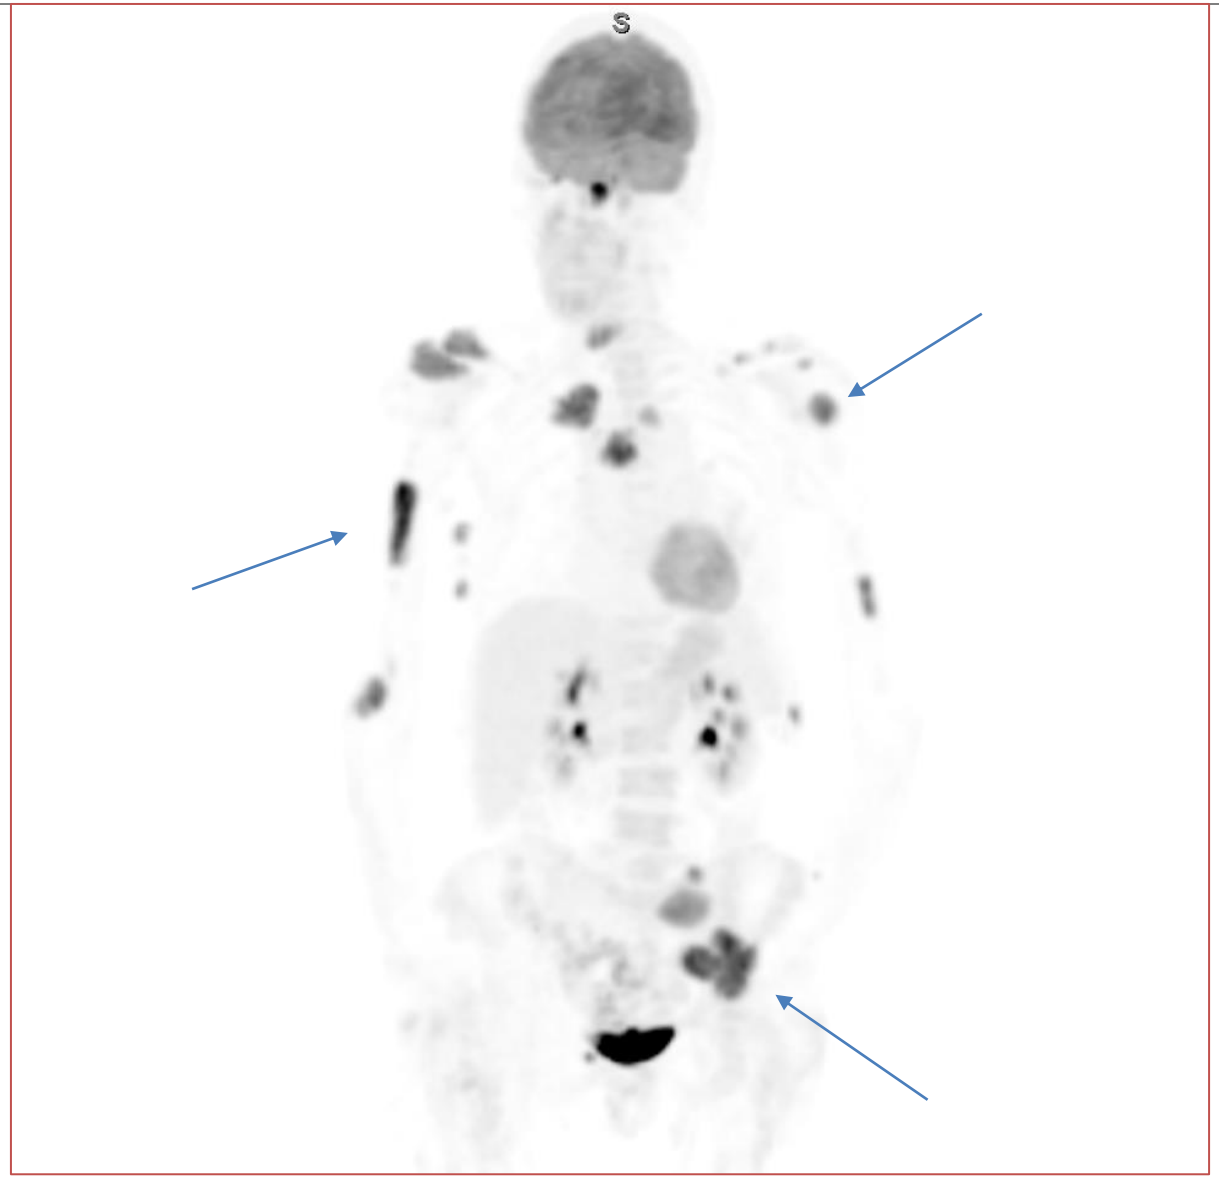
Initial presentation

- 61 yo woman, otherwise healthy, presented to ER with back pain.
- MRI of lumbar spine: multiple lytic lesions in lower T spine + bony pelvis with pathologic fracture of T9.
- Initial laboratory evaluations ultimately showed:
  - SPEP: M-spike 2.85 g/dL
  - FKLC: 1.2 mg/dL
  - FLLC 132 mg/dL
  - sFLCr ratio: 110
  - Hemoglobin: Normal
  - Creatinine: Normal
  - Calcium: Normal
  - Serum Immunoglobulins
    - IgM 23 mg/dl
    - IgA 2431 mg/dl
    - IgG 590 mg/dl

Bone marrow Biopsy

- Plasma cell neoplasm, comprising approximately 10% of marrow cellularity.
- Hypercellular marrow with trilineage hematopoiesis.
- CD138 stains plasma cells which are scattered or in aggregate and are lambda restricted.
- Flow Cytometry: Abnormal plasma cell population with cytoplasmic lambda light chain restriction with abnormal expression of CD27 (decreased) with normal expression of CD19, CD38 and CD138 without CD56 or CD117.
- Cytogenetics: no significant deletions or re-arrangement detected
- FISH: t(14:16), 1q gain

PET/CT



Treatment

- She completed 8 cycles of bortezomib, lenalidomide, dexamethasone (VRd) with a response of VGPR
- Although stem cell harvest was completed. Patient opted to hold off on transplant and save for further down the line
- EOT BMBx: without evidence of plasma cell population-MRD+. Myeloid hyperplasia noted
- EOT PET/CT showed new FDG avid soft tissue densities on right breast. Breast ultrasound showed 3 masses on right breast concerning for malignancy. Breast biopsy pathology revealed TNBC invasive ductal carcinoma.

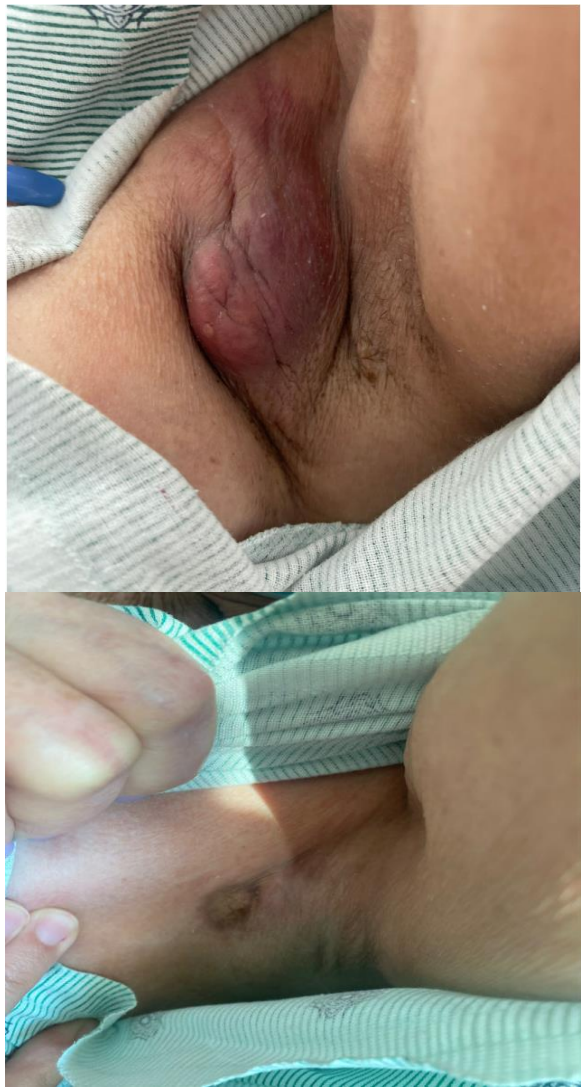
Stage 2 TNBC

- After receiving one cycle of lenalidomide maintenance. It was stopped to prioritize, curative intent treatment for breast cancer starting with neoadjuvant therapy.
- She was treated with keynote 522, and received pembro-AC.
- As she started pembro-CbT, decision was made that her myeloma was flaring (presentation of new plasmacytomas) and she needed to stop breast NACT and restart myeloma directed treatment and proceeded with 2 cycles of therapy with daratumumab, carfilzomib, dexamethasone (DKd) and pembrolizumab.

Progression and complications

- After cycle 2 of DKd she was admitted to the hospital for acute compression of the spinal cord with numbness and decreased power of her lower extremities at the beginning, requiring T5-T7 laminectomy (pathology resulted on high grade metastatic myeloma).
- Imaging showed wide-spread abdominal tumor deposits including a large pelvic soft tissue mass, biopsy consistent with plasma cell myeloma.
- Started radiation therapy for symptomatic plasmacytomas and plans for third line treatment

Disease progression



UNIVERSITY OF MIAMI

Myeloma Division

Repeat Biopsy

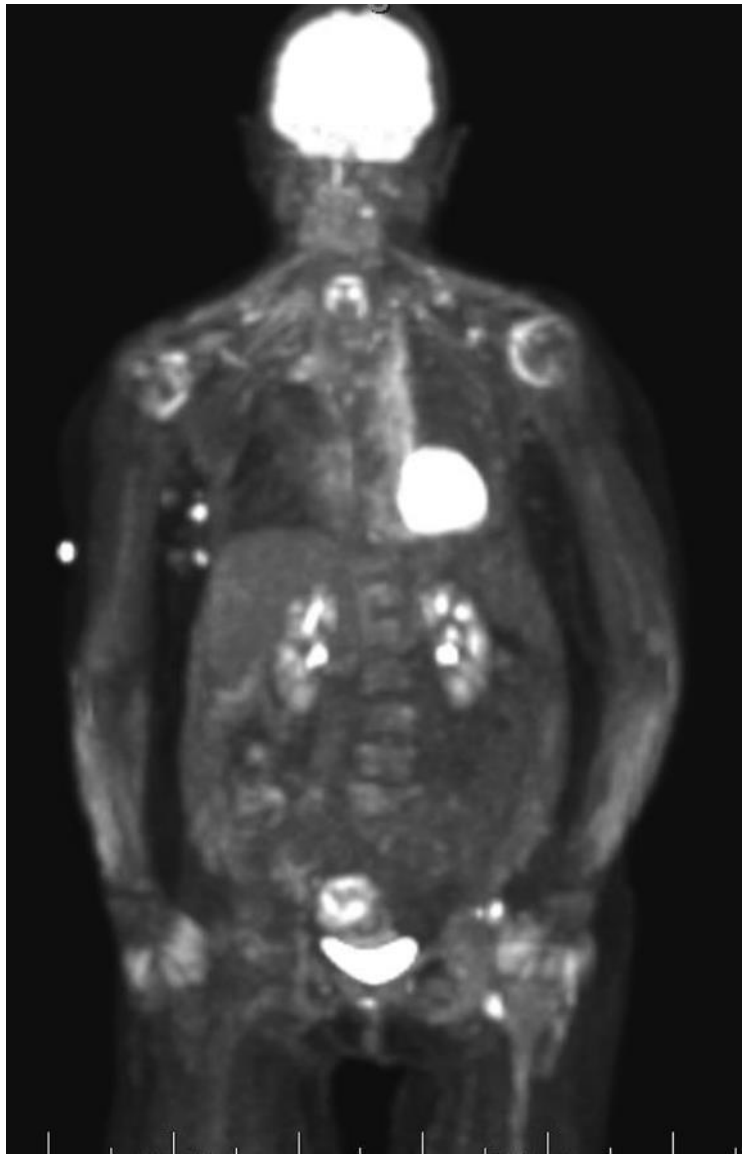
- Superficial tumors were proven to be plasmacytomas by pathology
- Bone marrow biopsy consistent with anaplastic plasma cells
- Patient was very symptomatic and DKd therapy resulted in a mixed response at best.
- Decision was made to “debulk her” with cytotoxic chemotherapy and “immuno-consolidate” with the bispecific T cell directing antibody, teclistamab which had just been FDA approved

Teclistamab

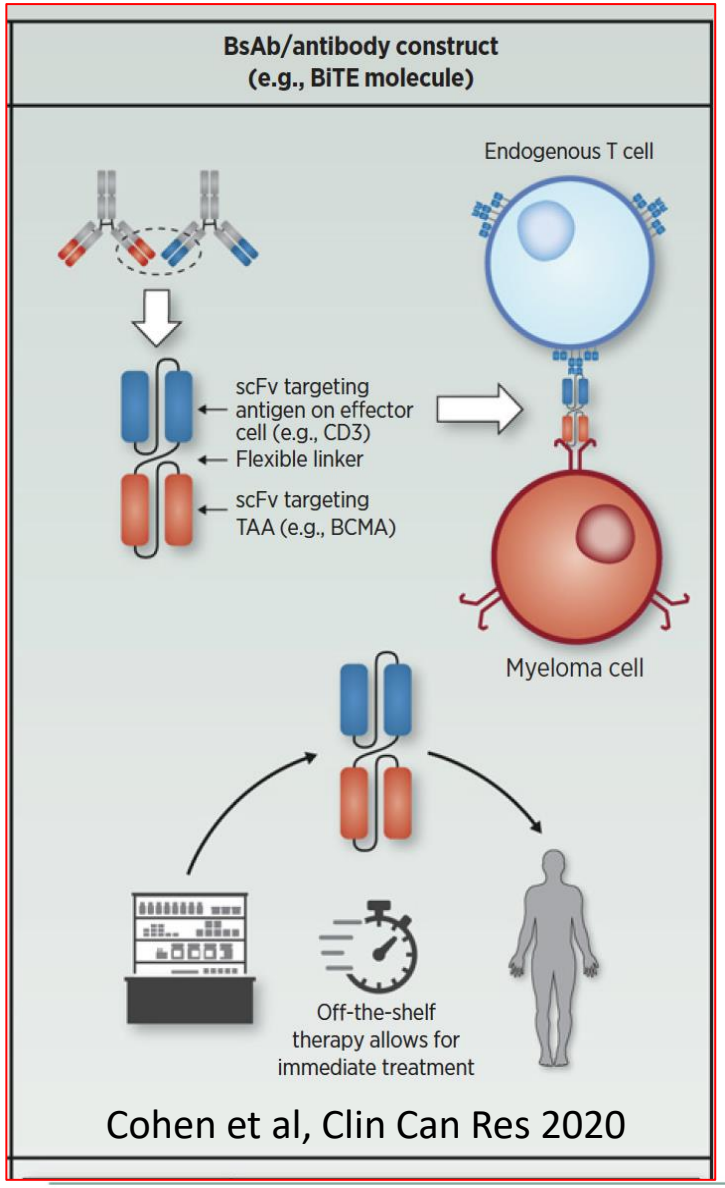
- She received 2 cycles of EPOCH inpatient with significant tumor reduction and was then started on teclistamab
- She received 2 step up doses and 1 full treatment dose of tec over a week inpatient and subsequently moved to weekly treatments as an outpatient
- She immediately reported less pain and reduction of her multiple tumors
- As her myeloma had become anaplastic and mostly extramedullary in manifestation and oligosecretory, myeloma labs not correlated with disease.

Teclistamab Response

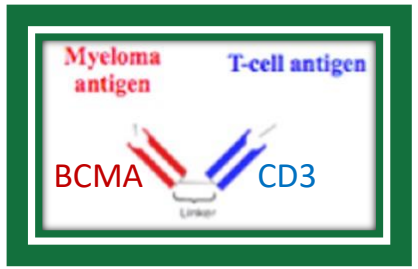
- After 2 cycles of teclistamab, PET/CT:
  - Interval significant improvement of previously seen multiple hypermetabolic osseous lesions
  - Redemonstration of hypermetabolic soft tissue lesions within the right breast overlying the breast implant with two new lesions as detailed above. These findings may represent myelomatous involvement or a second primary, consider tissue sampling if clinically indicated.
- Patient currently being reevaluated for mastectomy at which time pathology of lesions will be evaluated



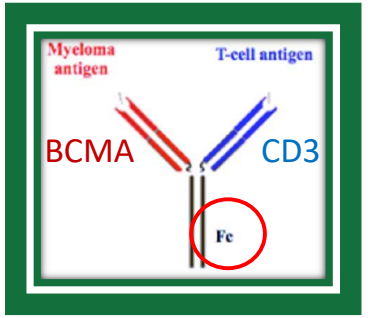
Discussion: BiSpecific T cell directing antibodies



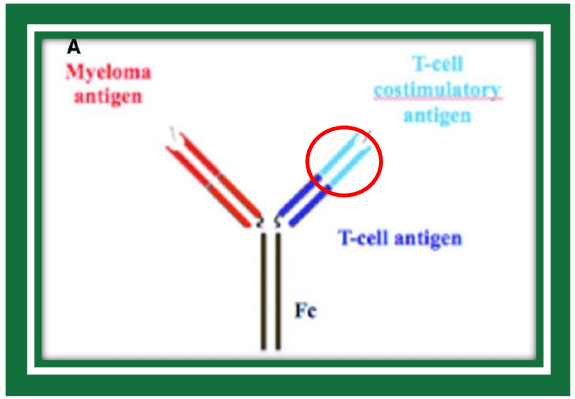
Cohen et al, Clin Can Res 2020



BiTE: Bispecific T cell Engager, AMG401
Short half-life



Bispecific Antibody: incorporation of Fc domain to extend half-life



Trispecific Antibodies: incorporation of both T cell antigen and costimulatory domain

Teclistamab, Furthest Developed Bispecific Ab Representative

Besemer, J. Martínez-López, S. Sidana, M. Delforge, L. Pei, D. Trancucci, R. Verona, S. Girgis, S.X.W. Lin, Y. Olyslager, M. Jaffe, C. Uhlar, T. Stephenson, R. Van Rampelbergh, A. Banerjee, J.D. Goldberg, R. Kobos, A. Krishnan, and S.Z. Usmani

Study Design: Phase 1/2

- A BCMA x CD3 BiSAb
- Weekly teclistamab after step-up doses
- Primary end point was ORR

Kazandjian, Kowalski, Landgren: Leuk Lymph 2022

Summary and conclusions

- Complicated case with a patient dealing with three different malignancies. Prioritizing which malignancy to treat was at the utmost importance
- Teclistamab use has thus far showed promising results in this aggressive case of multiple myeloma
- The use of teclistamab has provided enough disease control, to allow the patient to resume breast cancer management
- Bi-Specific T cell directing antibodies has significantly changed the landscape of myeloma treatment
